

# RELATIVE SIZE OF SUBSETS OF A SEMIGROUP

IGOR PROTASOV AND SERHII SLOBODIANIUK

**ABSTRACT.** Given a semigroup  $S$ , we introduce relative (with respect to a filter  $\tau$  on  $S$ ) versions of large, thick and prethick subsets of  $S$ , give the ultrafilter characterizations of these subsets and explain how large could be some cell in a finite partition of a subset  $A \in \tau$ .

## 1. INTRODUCTION

For a semigroup  $S$ ,  $a \in S$ ,  $A \subseteq S$  and  $B \subseteq S$ , we use the standard notations

$$a^{-1}B = \{x \in S : ax \in B\}, \quad A^{-1}B = \bigcup_{a \in A} a^{-1}B,$$

$$[A]^{<\omega} = \{F \subseteq A, F \text{ is finite}\}.$$

A subset  $A$  of  $S$  is called

- *large* if there exists  $F \in [S]^{<\omega}$  such that  $S = F^{-1}A$ ;
- *thick* if, for every  $F \in [S]^{<\omega}$ , there exists  $x \in S$  such that  $Fx \subseteq A$ ;
- *prethick* if  $F^{-1}A$  is thick for some  $F \in [S]^{<\omega}$ ;
- *small* if  $L \setminus A$  is large for any large subset  $L$ .

In the dynamical terminology [8, p.101], large and prethick subsets are known as syndetic and piecewise syndetic. These and several other combinatorially rich subsets of a semigroup are intensively studied in connection with the Ramsey Theory (see [8, Part III]). In [6], large, thick and prethick subsets are called right syndetic, right thick and right piecewise syndetic.

The names large and small subsets of a group appeared in [4], [5] with additional adjective "left". Unexplicitly, thick subsets were used in [11] to partition an infinite totally bounded topological group  $G$  into  $|G|$  dense subsets. For more delicate classification of subsets of a group by their size, we address the reader to [3], [9], [10], [14], [17], [18].

In frames of general asymptology [20, Chapter 9], large and thick subsets of a group could be considered as counterparts of dense and open subsets of a topological space.

Our initial motivation to this note was a desire to refine and generalize to semigroup the following statement [13, Corollary 3.4]: if a neighborhood  $U$  of the identity  $e$  of a topological group  $G$  is finitely partitioned then there exists a cell  $A$  of the partition and a finite subset  $F \subset U$  such that  $FAA^{-1}$  is a neighborhood of  $e$ . On this way, we run to some relative (with respect to a filter) versions of above definitions.

Let  $S$  be a semigroup and let  $\tau$  be a filter on  $S$ . We say that a subset  $A$  of  $S$  is

- $\tau$ -*large* if, for every  $U \in \tau$ , there exists  $F \subseteq [U]^{<\omega}$  such that  $F^{-1}A \in \tau$ ;
- $\tau$ -*thick* if there exists  $U \in \tau$  such that, for any  $F \in [U]^{<\omega}$  and  $V \in \tau$ , one can find  $x \in V$  such that  $Fx \subseteq A$ ;
- $\tau$ -*prethick* if, for every  $U \in \tau$ , there exists  $F \in [U]^{<\omega}$  such that  $F^{-1}A$  is  $\tau$ -prethick;
- $\tau$ -*small* if  $L \setminus A$  is  $\tau$ -large for every  $\tau$ -large subset  $L$ .

In the case  $\tau = \{S\}$ , we omit  $\tau$  and get the seminal classification of subsets of  $S$  by their size.

To conclude the introduction, we need some algebra in the Stone-Ćech compactifications from [8].

---

2010 *Mathematics Subject Classification.* 05D10, 20M12, 22A15.

*Key words and phrases.* large, thick and prethick subsets of a semigroup; ultrafilters; the Stone-Ćech compactification of a discrete semigroups; minimal left ideal.

For a discrete semigroup  $S$ , we consider the Stone-Ćech compactification  $\beta S$  of  $S$  as the set of all ultrafilters on  $S$ , identifying  $S$  with the set of all principal ultrafilters, and denote  $S^* = \beta S \setminus S$ . For a subset  $A$  of  $S$  and a filter  $\tau$  on  $S$ , we set

$$\overline{A} = \{p \in \beta S : A \in p\}, \quad \overline{\tau} = \bigcap \{\overline{A} : A \in \tau\} = \{p \in \beta S : \tau \subseteq p\}$$

and note that the family  $\{\overline{A} : A \subseteq S\}$  forms base for the open sets on  $\beta S$ , and each non-empty closed subset in  $\beta S$  is of the form  $\overline{\tau}$  for an appropriate filter  $\tau$  on  $S$ .

The universal property of the Stone-Ćech compactifications of discrete spaces allows to extend multiplication from  $S$  to  $\beta S$  in such way that, for any  $p \in \beta S$  and  $g \in S$  the shifts  $x \mapsto xp$  and  $x \mapsto gx$ ,  $x \in \beta S$  are continuous.

For any  $A \subseteq S$  and  $q \in \beta S$ , we denote

$$A_q = \{x \in S : x^{-1}A \in q\}.$$

Then formally the product  $pq$  of ultrafilters  $p$  and  $q$  can be defined [8, p.89] by the rule:

$$A \in pq \leftrightarrow A_q \in p.$$

In this note, we give the ultrafilter characterizations of  $\tau$ -large and  $\tau$ -thick subsets (section 2) and  $\tau$ -prethick subsets (section 3) in spirit of [6], [8], [18]. If  $\tau$  is a subsemigroup of  $\beta S$ , we describe the minimal left ideal of  $\overline{\tau}$  to understand how big could be the cells in a finite partition of a subset  $A \in \tau$ .

## 2. RELATIVELY LARGE AND THICK SUBSETS

Let  $\tau$  be a filter on a semigroup  $S$ .

**Theorem 2.1.** *A subset  $L$  of  $S$  is  $\tau$ -large if and only if, for every  $p \in \overline{\tau}$  and  $U \in \tau$ , we have  $L_p \cap U \neq \emptyset$ .*

*Proof.* We suppose that  $L$  is  $\tau$ -large and take arbitrary  $p \in \overline{\tau}$  and  $U \in \tau$ . We choose  $F \in [U]^{<\omega}$  such that  $F^{-1}L \in \tau$ . Since  $F^{-1}L = \bigcup_{g \in F} g^{-1}L$ , there exists  $g \in F$  such that  $g^{-1}F \in p$  so  $g \in L_p$  and  $L_p \cap U \neq \emptyset$ .

To prove the converse statement, we assume that  $L$  is not  $\tau$ -large and choose  $U \in \tau$  such that  $F^{-1}L \notin \tau$  for every  $F \in [U]^{<\omega}$ . Then we take an ultrafilter  $p \in \overline{\tau}$  such that  $G \setminus F^{-1}L \in p$  for each  $F \in [U]^{<\omega}$ . Clearly,  $g^{-1}L \notin p$  for every  $g \in U$  so  $U \cap L_p = \emptyset$ .  $\square$

**Theorem 2.2.** *A subset  $T$  of  $S$  is  $\tau$ -thick if and only if there exists  $p \in \overline{\tau}$  such that  $T_p \in \tau$ .*

*Proof.* We suppose that  $T$  is  $\tau$ -thick and pick corresponding  $U \in \tau$ . The set  $[U]^{<\omega} \times \tau$  is directed  $\leq$  by the rule:

$$(F, V) \leq (F', V') \leftrightarrow F \subseteq F', V' \subseteq V.$$

For each pair  $(F, V)$  we choose  $g(F, V) \in V$  such that  $Fg(F, V) \subseteq T$ . The family

$$P_{F,V} = \{g(F', V') : (F, V) \leq (F', V')\}, \quad (F, V) \in [U]^{<\omega} \times \tau$$

is contained in some ultrafilter  $p \in \overline{\tau}$ . By the construction,  $U \subseteq T_p$  so  $T_p \in \tau$ .

To prove the converse statement, we choose  $p \in \overline{\tau}$  such that  $T_p \in \tau$ . Given any  $F \in [T_p]^{<\omega}$  and  $V \in \tau$ , we take  $P \in p$  such that  $P \subseteq V$  and  $gP \subseteq T$  for each  $g \in F$ . Then we choose an arbitrary  $x \in P$  and get  $Fx \subseteq T$  so  $T$  is  $\tau$ -thick.  $\square$

We say that a subset  $T$  of  $S$  is  $\tau$ -extrathick if  $T_p \in \tau$  for each  $p \in \overline{\tau}$ .

By [6, Theorem 2.4], a subset  $T$  is thick if and only if  $T$  intersects each large subset non-trivially. In the case  $\tau = \{G\}$ , this is a partial case of the following theorem.

**Theorem 2.3.** *If each subset  $U \in \tau$  is  $\tau$ -extrathick then a subset  $T$  of  $S$  is  $\tau$ -thick if and only if  $T \cap L \cap U \neq \emptyset$  for any  $\tau$ -large subset  $L$  and  $U \in \tau$ .*

*Proof.* We assume that  $T$  is  $\tau$ -thick and use Theorem 2.2 to find  $p \in \bar{\tau}$  such that  $T_p \in \tau$ . We take an arbitrary  $\tau$ -large subset  $L$  and  $U \in \tau$ . Since  $U$  is  $\tau$ -extrathick, we have  $U_p \in \tau$ . By Theorem 2.1,  $L_p \cap (T_p \cap U_p) \neq \emptyset$ . If  $g \in L_p \cap T_p \cap U_p$  then  $L \in gp$ ,  $T \in gp$ ,  $U \in gp$ . Hence,  $T \cap L \cap U \neq \emptyset$ .

We suppose that  $T \cap L \cap U = \emptyset$  for some  $\tau$ -large subset  $L$  and  $U \in \tau$  but  $T$  is  $\tau$ -thick. We take  $p \in \bar{\tau}$  such that  $T_p \in \tau$ . Since  $U$  is  $\tau$ -extrathick, we have  $U_p \in \tau$ . By Theorem 2.1,  $L_p \cap (T_p \cap U_p) \neq \emptyset$ . If  $g \in L_p \cap T_p \cap U_p$  then  $L \in gp$ ,  $T \in gp$ ,  $U \in gp$ . Hence,  $T \cap L \cap U \neq \emptyset$  and we get a contradiction.  $\square$

**Theorem 2.4.** *Let  $g \in S$  and let  $\tau$  be a filter on  $S$  such that  $g^{-1}U \in \tau$  for each  $U \in \tau$ . If a subset  $L$  of  $S$  is  $\tau$ -large and a subset  $T$  of  $S$  is  $\tau$ -thick then  $gL$  and  $g^{-1}T$  are  $\tau$ -large and  $\tau$ -thick respectively.*

*Proof.* To prove that  $gL$  is  $\tau$ -large, we take an arbitrary  $U \in \tau$  and choose  $V \in \tau$  such that  $gV \subseteq U$  (using  $g^{-1}U \in \tau$ ). Since  $L$  is  $\tau$ -large, there is  $F \in [V]^{<\omega}$  such that  $F^{-1}L \in \tau$ . We note that  $F^{-1}L = (gF)^{-1}gF$ . Since  $gF \in [U]^{<\omega}$ , we conclude that  $gF$  is  $\tau$ -large.

To see that  $g^{-1}T$  is  $\tau$ -thick, we pick  $U \in \tau$  such that, for every  $F \in [U]^{<\omega}$  and  $W \in \tau$ , there is  $x \in W$  such that  $Fx \subseteq T$ . We choose  $V \in \tau$  such that  $gV \subseteq U$ . Then we take an arbitrary  $H \in [V]^{<\omega}$  and  $W \in \tau$ . Since  $gH \in [U]^{<\omega}$ , there exists  $y \in W$  such that  $gHy \subseteq T$  so  $Hy \subseteq g^{-1}T$  and  $g^{-1}T$  is  $\tau$ -thick.  $\square$

We say that a family  $\mathcal{F}$  of subsets of  $S$  is *left (left inverse) invariant* if, for any  $A \in \mathcal{F}$  and  $g \in S$ , we have  $gA \in \mathcal{F}$  ( $g^{-1}A \in \mathcal{F}$ ).

**Corollary 2.1.** *If  $\tau$  is inverse invariant then the family of all  $\tau$ -large ( $\tau$ -thick) subsets is left (left inverse) invariant.*

**Theorem 2.5.** *Let  $\tau$  be a filter on  $S$  such that, for every  $U \in \tau$ , we have  $\{g \in S : g^{-1}U \in \tau\} \in \tau$ . If  $T$  is  $\tau$ -thick then there exists  $V \in \tau$  such that  $g^{-1}T$  is  $\tau$ -thick for every  $g \in V$ .*

*Proof.* We take  $U \in \tau$  such that, for any  $K \in [U]^{<\omega}$  and  $W \in \tau$ , we have  $Kx \subseteq T$  for some  $x \in W$ . Then we choose  $V \in \tau$  such that, for every  $g \in V$ , there exists  $V_g \in \tau$  with  $gV_g \subseteq U$ . Given any  $F \in [V_g]^{<\omega}$  and  $W \in \tau$ , we pick  $x \in W$  such that  $gFx \subseteq T$  so  $Fx \subseteq g^{-1}T$  and  $g^{-1}T$  is  $\tau$ -thick.  $\square$

A topology  $\mathcal{T}$  on a semigroup  $S$  is called *left invariant* if each left shift  $x \mapsto gx$ ,  $g \in G$  is continuous (equivalently, the family  $\mathcal{T}$  is left inverse invariant).

We assume that  $S$  has identity  $e$  and say that a filter  $\tau$  on  $S$  is *left topological* if  $\tau$  is the filter of neighborhoods of  $e$  for some (unique in the case if  $S$  is a group) left invariant topology  $\mathcal{T}$  on  $S$ .

Let  $\tau$  be a left topological filter on  $S$ . Then each subset  $U \in \tau$  is  $\tau$ -extrathick and  $\tau$  satisfies Theorem 2.5. Hence, Theorems 2.3 and 2.5 hold for  $\tau$ .

We show that Theorem 2.5 needs not to be true with  $\tau$ -large subsets in place of  $\tau$ -thick subsets even if  $\tau$  is a filter on neighborhoods of the identity for some topological group.

We endow  $\mathbb{R}$  with the natural topology, denote  $\mathbb{R}^+ = \{r \in \mathbb{R}, r > 0\}$  and take the filter  $\tau$  of neighborhoods of 0. The set  $\mathbb{R}^+$  is  $\tau$ -large because  $\mathbb{R}^+ - x \in \tau$  for each  $x \in \mathbb{R}^+$ . On the other hand,  $\mathbb{R}^+ + x$  is not  $\tau$ -large for each  $x \in \mathbb{R}^+$ .

### 3. RELATIVELY PRETHICK SUBSETS

We say that a filter  $\tau$  on  $S$  is a *semigroup filter* if  $\bar{\tau}$  is a subsemigroup of the semigroup  $\beta S$  and note that, if either  $\tau$  is inverse left invariant or  $S$  has the identity and  $\tau$  is left topological then  $\tau$  is a semigroup filter.

In the case  $\tau = \{S\}$ , the following statement is Theorem 4.39 from [8].

**Theorem 3.1.** *Let  $\tau$  be a semigroup filter on  $S$ . An ultrafilter  $p \in \bar{\tau}$  belongs to some minimal left ideal  $L$  of  $\bar{\tau}$  if and only if, for each  $A \in p$ , the set  $A_p$  is  $\tau$ -large.*

*Proof.* Let  $L$  be a minimal left ideal of  $\bar{\tau}$ ,  $p \in L$ ,  $A \in p$  and  $U \in \tau$ . Clearly,  $L = \bar{\tau}p$ . We take an arbitrary  $r \in \tau$ . By the minimality of  $L$ ,  $\bar{\tau}rp = \bar{\tau}p$ , so there exists  $q_r \in \tau$  such that  $q_r rp = p$ . Since  $A \in q_r rp$  and  $U \in q_r$ , by the definition of the multiplication in  $\beta S$ , there exists  $B_r \in r$  such that  $\overline{B_r p} \subseteq \overline{x_r^{-1}A}$ . We consider the open cover  $\{\overline{B_r}, r \in \bar{\tau}\}$  of the compact space  $\bar{\tau}$  and choose its finite

subcover  $\{\overline{B}_r : r \in K\}$ . We put  $B = \bigcup_{r \in K} B_r$ ,  $F = \{x_r, r \in K\}$ . Then  $B \in \tau$  and  $B \subseteq (F^{-1}A)_p$ . By the choice,  $F \subseteq U$ . Since  $p$  is an ultrafilter, we have  $(F^{-1}A)_p = F^{-1}A_p$ . Hence,  $A_p$  is  $\tau$ -large.

To prove the converse statement we suppose that  $\overline{\tau}p$  is not minimal and choose  $r \in \overline{\tau}$  such that  $p \notin \overline{\tau}rp$ . Since the subset  $\tau rp$  is closed in  $\overline{\tau}$ , there exists  $A \in p$  with  $\overline{A} \cap \overline{\tau}rp = \emptyset$ . It follows that  $A \notin qrp$  for every  $q \in \overline{\tau}$ . Hence,  $S \setminus A \in qrp$  for every  $q \in \overline{\tau}$ . It follows that there exists  $U \in \tau$  such that  $x^{-1}(G \setminus A) \in rp$  for each  $x \in U$ . By the assumption, there exists  $F \in [U]^{<\omega}$  such that  $F^{-1}A \in qp$  for every  $q \in \overline{\tau}$ . In particular,  $x^{-1}A \in rp$  for some  $x \in F$  and we get a contradiction.  $\square$

**Corollary 3.1.** *Let  $\tau$  be a semigroup filter on  $S$  and let  $p \in \overline{\tau}$  belongs to some minimal left ideal of  $\overline{\tau}$ . Then every subset  $A \in p$  is  $\tau$ -prethick.*

*Proof.* Given an arbitrary  $U \in \tau$ , we use Theorem 3.1 to find  $F \in [V]^{<\omega}$  such that  $(F^{-1}A)_p \in \tau$ . By Theorem 2.2,  $F^{-1}A$  is  $\tau$ -thick. Hence,  $A$  is  $\tau$ -prethick.  $\square$

**Corollary 3.2.** *Let  $\tau$  be a semigroup filter on a group  $G$  and let  $U \in \tau$ . Then, for every finite partition  $\mathcal{P}$  of  $U$  and every  $V \in \tau$ , there exists  $A \in \mathcal{P}$  and  $F \in [V]^{<\omega}$  such that  $F^{-1}AA^{-1} \in \tau$ .*

*Proof.* We take  $p$  from some minimal left ideal of  $\overline{\tau}$ . Then we choose  $A \in \mathcal{P}$  such that  $A \in p$ . Applying Theorem 3.1, we find  $F \in [V]^{<\omega}$  such that  $(F^{-1}A)_p \in \tau$ . If  $x \in (F^{-1}A)_p$  then  $F^{-1}A \in xp$  and  $x \in F^{-1}AA^{-1}$ . Hence,  $F^{-1}AA^{-1} \in \tau$ .  $\square$

In connection with Corollary 3.2, we would like to mention one of the most intriguing open problem in the subset combinatorics of groups [12, Problem 13.44] posed by the first author in 1995: given any group  $G$ ,  $n \in \mathbb{N}$  and partition  $\mathcal{P}$  on  $G$  into  $n$  cells, do there exist  $A \in \mathcal{P}$  and  $F \subseteq G$  such that  $G = FAA^{-1}$  and  $|F| \leq n$ ? For recent state of this problem see the survey [2].

On the other hand [1], if an infinite group  $G$  is either amenable or countable, then for every  $n \in \mathbb{N}$ , there exists a partition  $G = A \cup B$  such that  $FA$  and  $FB$  are not thick for each  $F$  with  $|F| \leq n$ . We do not know whether such a 2-partition exists for any uncountable group  $G$  and  $n \in \mathbb{N}$ .

**Theorem 3.2.** *Let  $G$  be a group,  $\tau$  be a filter of neighborhoods of the identity for some group topology on  $G$  and  $U \in \tau$ . Then, for any partition  $\mathcal{P}$  of  $U$ ,  $|\mathcal{P}| = n$  and  $V \in \tau$ , there exist  $A \in \mathcal{P}$  and  $K \subseteq V$  such that  $KAA^{-1} \in \tau$  and  $K \leq 2^{2^{n-1}-1}$ .*

*Proof.* We consider only the case  $n = 2$ . For  $n > 2$ , the reader can adopt the inductive arguments from [16, pp. 120-121], where this fact was proved for  $\tau = \{G\}$ . So let  $U = A \cup B$  and  $e \in B$ . We choose  $W \in \tau$  such that  $WW \subseteq U$  and denote  $C = A \cap W$ . If there exists  $H \in \tau$  such that  $xC \cap C \neq \emptyset$  for each  $x \in H$  then  $CC^{-1} \in \tau$  and we put  $F = \{e\}$ , so  $F^{-1}AA^{-1} \in \tau$ . Otherwise, we take  $g \in V \cap W$  such that  $gC \cap C = \emptyset$ . Then  $gC \subseteq WW \subseteq U$ , so  $gC \subseteq B$  and  $B \cup g^{-1}B \in \tau$ . We put  $F = \{e, g\}$ . Since  $e \in B$ , we have  $F^{-1}BB^{-1} \in \tau$ .  $\square$

Recall that a family  $\mathcal{F}$  of subsets of a set  $X$  is *partition regular* if, for every  $A \in \mathcal{F}$  and any finite partition of  $A$ , at least one cell of the partition is a member of  $\mathcal{F}$ .

For a subsemigroup filter  $\overline{\tau}$  on  $S$ , we denote by  $M(\overline{\tau})$  the union of all minimal left ideals of  $\overline{\tau}$ . In the case  $\tau = \{G\}$ , the following statement is Theorem 4.40 from [8].

**Theorem 3.3.** *Let  $\tau$  be left inverse invariant filter on a semigroup  $S$ . Then the following statements hold*

- (i) *a subset  $A$  of  $S$  is  $\tau$ -prethick if and only if  $\overline{A} \cap M(\overline{\tau}) \neq \emptyset$ ;*
- (ii)  *$P \in clM(\overline{\tau})$  if and only if each  $A \in p$  is  $\tau$ -prethick;*
- (iii) *the family of all  $\tau$ -prethick subsets of  $S$  is partition regular.*

*Proof.* (i) If  $\overline{A} \cap M(\overline{\tau}) \neq \emptyset$  then  $A$  is  $\tau$ -prethick by Corollary 3.1.

Assume that  $A$  is  $\tau$ -prethick and pick a finite subset  $F$  such that  $F^{-1}A$  is  $\tau$ -thick. We use Theorem 2.2 to find  $p \in \overline{\tau}$  such that  $(F^{-1}A)_p \in \tau$ . Then  $F^{-1}A \in qp$  for every  $q \in \overline{\tau}$ . The set  $\overline{\tau}p$  contains some minimal left ideal  $L$  of  $\overline{\tau}$ . We take any  $r \in L$  so  $F^{-1}A \in r$  and  $A \in tr$  for some  $t \in F$ . Since  $\tau$  is inverse left invariant  $tr \in \overline{\tau}$ . Hence,  $tr \in M(\overline{\tau}) \cap \overline{A}$ .

The statements (ii) and (iii) follow directly from (i).  $\square$

**Theorem 3.4.** *Let  $\tau$  be a left invariant filter on a group  $G$ . A subset  $A$  of  $G$  is  $\tau$ -prethick if and only if  $A$  is not  $\tau$ -small.*

*Proof.* By the definition and Theorem 2.4, the family of all  $\tau$ -small subsets of  $G$  is left invariant and invariant under finite unions. We suppose that  $A$  is  $\tau$ -small and  $\tau$ -prethick and take  $K \in [G]^{<\omega}$  such that  $KA$  is  $\tau$ -thick. We note that  $G$  is  $\tau$ -large and  $KA$  is  $\tau$ -small so  $G \setminus KA$  is  $\tau$ -large. But  $(G \setminus KA) \cap KA = \emptyset$  and we get a contradiction with Theorem 2.3.  $\square$

We do not know whether Theorems 3.3 and 3.4 hold for any left topological filter  $\tau$  (even for filters of neighborhoods of identity of topological groups).

For a subset  $A$  of an infinite group  $G$ , we denote

$$\Delta(A) = \{x \in G : xA \cap A \text{ is infinite}\}.$$

Answering a question from [15], Erde proved [7] that if  $A$  is prethick then  $\Delta(A)$  is large. We conclude the paper with some relative version of this statement.

For a filter  $\tau$  on a semigroup  $S$  and  $A \subseteq S$ , we denote

$$\Delta_\tau(A) = \{x \in S : (x^{-1}A \cap A) \cap U \neq \emptyset \text{ for any } U \in \tau\}.$$

In the case of a group  $G$ ,  $\Delta(A) = (\Delta(A))^{-1}$  so we have  $\Delta(A) = \Delta_\tau(A)$  for the filter  $\tau$  of all cofinite subsets of  $G$ .

**Theorem 3.5.** *Let  $\tau$  be a left inverse invariant filter on a semigroup  $S$ . If a subset  $A$  of  $S$  is  $\tau$ -prethick then  $\Delta_\tau(A)$  is  $\tau$ -large.*

*Proof.* We observe that  $\Delta_\tau(A) = \bigcup \{A_p : p \in \bar{\tau}, A \in p\}$ . Now let  $A$  be  $\tau$ -prethick. We use Theorem 3.3(i) to find  $p \in \bar{A} \cap M(\bar{\tau})$ . By Theorem 3.1, for every  $U \in \tau$ , there exists a finite subset  $K \subseteq U$  such that  $K^{-1}A_p \in \tau$ . Since  $A_p \subseteq \Delta_\tau(A)$ , we have  $K^{-1}\Delta_\tau(A) \in \tau$ , so  $\Delta_\tau(A)$  is  $\tau$ -large.  $\square$

Let  $\tau$  be a left invariant filter on a group  $G$  and let  $X \subseteq G$ . Then  $\Delta_\tau(X) = \{g \in G : (gX \cap X) \cap U \neq \emptyset \text{ for each } U \in \tau\}$  and  $\Delta_\tau(X \setminus U) = \Delta_\tau(X)$  for each  $U \in \tau$ . Now let  $\tau$  be left invariant and  $G \setminus K \in \tau$  for each  $K \in [G]^{<\omega}$ . By [2, Proposition 2.7], for every  $n$ -partition  $\mathcal{P}$  of  $G$ , there exists  $A \in \mathcal{P}$  and  $F \in [G]^{<\omega}$  such that  $F\Delta_\tau(A) \in \tau$  and  $|F| \leq n!$ . This statement and above observations imply that, for any  $U \in \tau$  and  $n$ -partition  $\mathcal{P}$  of  $U$ , there exist  $F \in [G]^{<\omega}$  and  $A \in \mathcal{P}$  such that  $|F| \leq n!$  and  $F\Delta_\tau(A) \in \tau$ . Moreover, for any pregiven  $V \in \tau$ ,  $F$  can be chosen from  $V^{-1}$ . Indeed, we take  $x \in \bigcap_{g \in F} gV$  so  $F^{-1}x \subseteq V$  and  $x^{-1}F\Delta_\tau(A) \in \tau$ .

**Question 3.1.** *Let  $\tau$  be a filter of neighborhoods of the identity for some group topology on a group  $G$  and let  $U \in \tau$ . Given any  $n$ -partition  $\mathcal{P}$  of  $U$  and  $V \in \tau$ , do there exist  $A \in \mathcal{P}$  and  $F \subseteq V$  such that  $FAA^{-1} \in \tau$  and  $|F| \leq n!$*

By Theorem 3.2, the answer to Question 3.1 is positive with  $2^{2^n}$  in place of  $n!$ , .

**Question 3.2.** *Does there exist a function  $f : \mathbb{N} \rightarrow \mathbb{N}$  such that for any group  $G$ , a filter  $\tau$  of a group topology on  $G$ ,  $U \in \tau$  and an  $n$ -partition  $\mathcal{P}$  of  $U$ , there are  $A \in \mathcal{P}$  and  $K \in [G]^{<\omega}$  such that  $K\Delta_\tau(A) \in \tau$  and  $|K| \leq f(n)$ ? If yes, then can  $K$  be chosen from pregiven  $V \in \tau$ ?*

We conjecture the positive answer to Question 3.2 with  $f(n) = 2^{2^n}$  (or even with  $f(n) = n!$ ).
